SYSTRAN PremiumÂ . download download the basis for the argumentation which will be carried out in the following sections. Applying Software and Its Impact on Performance It is necessary to study the work of high-level language run-time environments while running a software application that implements Java or C#. Using instruction trace data, it becomes apparent that the time spent executing software code is sometimes made up of up to a half of the total execution time of the program (if running with just 1 core). Fruhmorgen et al. [4] showed that the performance of a Java software application can vary significantly depending on the platform it is run on. In addition, during the study, the authors found that the differences between software applications compiled to run on many-core systems compared to those compiled for a single-core platform, even when running with the same number of virtual processors and threads, increased. However, they concluded that differences were evident mainly between the same application running on a single-core system and those running on a many-core one. This applies to all applications, if the software is compiled for the respective platform. In this section, the authors will show how the nature and extent of the difference affects the overall execution time of the software application. Using 32-bit Windows XP virtual machines on an Intel(R) Core(TM) 2 Duo processor @ 2 GHz with 4 GB RAM and using a Java 7 platform JRE, they observed that with a software application running with 256 virtual processors on a 4-core system, the time used to execute a method call sometimes took twice the time of that same method call run on a single core, while that of a single-thread application with 32 virtual processors took exactly the same time as running with only 8 virtual processors. The authors conclude that in general, the time spent on execution is less of a problem on a many-core system than on a single-core system, because for the same application, the execution time is shorter, but also because on a single-core system, the other needs that the system usually handles in the background sometimes do not get any attention, but they are nevertheless important. On a many-core system, the impact of the effects of these different tasks
